Expected Value and Variance 6.1 Expected Value of Discrete Random Variables When a large collection of numbers is assembled, as in a census, we are usually interested not in the individual numbers, but rather in certain descriptive quantities such as the average or the median. In general, the same is true for the probability

Let X be any random variable with finite expected value and variance. Then for every positive real number a , $P(|X - E(X)| \geq a) \leq \frac{\text{Var}(X)}{a^2}$. There is a direct proof of this inequality in Grinstead and Snell (p. 305) but we can also prove it using Markov's inequality! Proof. Let $Y = (X - E(X))^2$.

Expected Value of a Function of a Continuous Random Variable Remember the law of the unconscious statistician (LOTUS) for discrete random variables: $E[g(X)] = \sum_{x_k \in R_X} g(x_k)P_X(x_k)$ (4.2) Now, by changing the sum to integral and changing the PMF to PDF we will obtain the similar formula for continuous random variables.

Moreover, it determines the degree to which the values of a random variable differ from the expected value. Generally, it shows how spread are the outcomes. The variance of a random variable X is the expected value of the squared deviation from the expected value of X . As a result, it's defined with $\text{Var}X = E[(X - EX)^2]$ We have

The expected value of a constant is just the constant, so for example $E(1) = 1$. Multiplying a random variable by a constant multiplies the expected value by that constant, so $E[2X] = 2E[X]$. A useful formula, where a and b are constants, is: $E[aX + b] = aE[X] + b$ [This says that expectation is a linear operator]. Variance

Expected Value for a Linear Combination of Random Variables. The expected value for a linear combination of random variables is conveniently quite simple to calculate. Say we have a two random variables X and Y , and that $E(X) = \mu_X$ and $E(Y) = \mu_Y$. Now suppose we have a random variable $Z = aX + bY + c$.

Properties of the data are deeply linked to the corresponding properties of random variables, such as expected value, variance and correlations. Dependencies between random variables are crucial factor that allows us to predict unknown quantities based on known values, which forms the basis of supervised machine learning.
